Please Please Please use Linux/Mac (Mac ? :|)

This is a quick note I created as I tried many of this setup things before, please read it carefully as it will really help you while setup your environment.

Version control

Install git, you are **FORCED** to do !

Ruby environment and package management

You can install any environment manager for ruby, such as **rbenv**,rvm or any other one I used rvm and rbenv and I recommend using rbenv.

Here you can find an awesome walk-through for installing it

> Please be careful and make a quick post-scan before copying and pasting commands, this will make your life easier **check the .bashrc config instead of .bash_profile for ubuntu for example**
>
> Please double check steps with other distros.

Also, this is a cool plugin for not running the silly `rbenv rehash` each time you install/uninstall a gem

Don't install node when the tutorial asks you for, we will install it from source better for some package compatibility later

NodeJS

I found that they now suggest this bash script that makes it for you, I didn't try it yet but it looks cool

For node installation I would prefer building it from source, download the **source code** from here

After this it's **highly recommended** to fix the permissions for global node modules, you can check the **2nd** option here

Text Editor

Use anything, if you are going to use some IDE please make sure you gitignore it's files, support me and use atom :smiley:

That's it for the current setup I think, Others will be later, if you need to get some of them from now because your internet speed is good consider downloading Android studio, PostMan or any RESTful API interaction app.
